Abstract

**Aim:** Laparoscopic surgery is getting more and more important. Compared with open surgery there are several advantages of laparoscopic surgery for instance fewer complications and a decreased postoperative hospital stay. Especially important during the initial learning phase of surgeons are cognitive abilities. They can be trained and tested on virtual reality simulators for laparoscopic surgery. In the current study the relationship between cognitive abilities and performance on a laparoscopic simulator is examined. It is expected that visuo-spatial ability and spatial memory are the best predictors for initial performance on a laparoscopic simulator. The findings could be used to develop training and assessment for surgeons, which consequently could decrease complications during laparoscopic surgery.

**Method:** 28 participants had to do cognitive aptitude tests on a computer to measure visuo-spatial ability, spatial memory, reasoning ability and processing speed. After that participants had up to 6 session of 30 minutes time on a virtual reality simulator for laparoscopic surgery. They had to pass two tasks on the simulator (“cutting” and “clip applying”). For the data-analyses different regression analyses were performed.

**Results:** Processing speed has the highest correlation with performance. On the cutting task there is a significant correlation between processing speed and tissue damage. The correlations between visuo-spatial ability and spatial memory with the dependent variables of performance are weak.

**Discussion:** The cognitive abilities had only limited predicting values in this study. The best predictors were processing speed and reasoning ability. The expectations could not be confirmed. Visuo-spatial ability and spatial memory had only weak a relation with performance. It is possible that the results are mediated by technical problems with the simulator. The results show that the relations between cognitive abilities and performance on a simulator are complex. It is necessary to do more research on this topic in order to develop suitable assessment and training for surgeons.

Introduction

Nowadays surgeons use minimally invasive surgery to a greater extent than ever before. In the past ten years there has been a remarkable increase in the usage of minimally invasive surgery and this development is ongoing in the future (Lee-Kong & Feingold, 2013). Therefore research on this kind of surgery is getting more and more important.

One kind of minimally invasive surgery is laparoscopic surgery. In this kind of surgery a small incision near the navel is made for the surgical equipment such as scissors or tools for cauterization as well as a laparoscope with a camera (Zadeh & Daftary, 2004, Luursema, Buzink, Verwey & Jakimowicz, 2012). The pictures made by this camera are displayed on a monitor. Via this monitor the surgeon is getting insight into the tissue and the target area (NICE, 2004). Handling the instruments, camera and display at the same time is difficult and leads to problems with for example the hand-eye coordination and navigation during the surgery (Gallagher & Smith, 2003). Research has shown that learning and training of minimally invasive surgery is more difficult than for open surgery. Additionally research indicates that there could be a relation between the learning curve and the surgeon’s cognitive abilities (Gallagher & Smith, 2003). The results of this study could be very useful in the future as they can be used to develop tools for training or selection and assessment of surgeons in minimally invasive surgery (Carroll, Kennedy, Traynor & Gallagher, 2009).

Minimally invasive surgery differs from open surgery in several ways and it has got some advantages compared to open surgery. The postoperative hospital stay after a laparoscopic surgery is up to 32 percent shorter than after an open surgery. Furthermore there are no special preparations necessary before the operation, for this reason the total stay in the hospital is also shorter. Relating to mortality and morbidity no difference has been detected (Veldkamp, 2005; King, 2006). Using minimally invasive surgery also less postoperative complications and infections arise (Aziz, 2006). Last but not least patients describe laparoscopic surgery as quite acceptable (King, 2006).

Although there are several positive aspects about laparoscopic surgery, there are also some disadvantages in comparison with open surgery. One example is that the average time for a laparoscopic surgery is 30 minutes longer than for an open surgery (Veldkamp, 2005). In comparison with normal surgery there are fewer complications during laparoscopic surgery, but the reasons for the complications differ from those that appear during open
surgery. During laparoscopic surgery complications with the equipment can occur, for example when the camera or the display is not properly working. Furthermore there are perceptual problems which do not occur in open surgery. They arise mainly through the fact that surgeons have to work with the 2D monitor image during the surgery. The surgeons have to interpret this picture made by a single camera source and translate it into 3D information. Usually depth is created by the two different views of the eyes, called binocular information. Missing this depth information, the display contributes to the spatial problems of the surgeon. Furthermore the fact that the surgeon has to view on the monitor which displays the surgery in a different perspective and magnification makes the hand–eye coordination much more difficult, which can lead to complications (Gallagher & Smith, 2003). Besides that, one of the main problems is the fulcrum effect created by the body wall. A movement to the left side is displayed as a movement to the right, which leads to disorientation (Gallagher & Smith, 2003). So a paradoxical movement can occur. In addition tactile and haptic feedback are missing. Those problems are making the surgery more difficult and can lead to complications if they are not handled in a right way (Gallagher & Smith, 2003).

Even though there are spatial problems and difficult circumstances during minimally invasive surgery, surgeons can be trained and get more experienced so that they would make fewer mistakes. Therefore it is important to improve introduction, selection and assessment of surgeons. The aim of this study is to understand the learning processes. From investigation we know that 90% of the complications occur during the first 30 minimally-invasive surgeries of a surgeon (The Southern Surgeons Club, 1995). Training for open operations happens mostly in the operation room. Beginners observe surgeries of professionals. After they have observed for several times, they are allowed to perform surgery on their own (Ahlberg et al., 2007). Ahlberg et.al (2007) stated that this way to train open surgery is inadequate for minimally invasive surgery. This is due to the fact that surgeons cannot learn to handle the special circumstances of minimally invasive surgery through observation, because they only see what is happening on the display. This way they cannot get a sensation about how deal with special problems like the fulcrum effect (Ahlberg et al, 2007).

Ahlberg et.al (2007) explain that the learning and education of novice surgeons can be improved through training via virtual reality simulators. Feldman, Sherman and Fried (2004) agree with that and state that training with a simulator is the best way because minimally invasive surgery can be simulated well and without dangers. Seymour, Gallagher, Roman, O'Brien, Bansal and Anderson (2002) have shown that surgeons trained for laparoscopic surgery with a virtual reality simulator are slightly faster in real surgery than surgeons trained
in a standard way. Additionally the mean number of errors occurring during a surgery is significantly greater when people are trained in the standard way then via the simulator. Using those simulators it can be seen that the learning process and performance times to reach expertise are much faster for open surgery than for laparoscopic surgery (Spaun, Zheng, Martinec, Arnold, Swenstroem, 2010). This can also be seen in the learning curves of surgical trainees. Novice surgeons are getting faster and making fewer mistakes after they have done several training sessions on a simulator (Voitk, 2001). Simulators are a good possibility to train surgeons and they are valid to measure the performance of surgeons. For this reason in this study we also use virtual reality simulators.

Although the simulator gives good guidance to practice laparoscopic surgery there are differences how fast people reach a professional level of minimally invasive surgery (Seymor et al., 2002, Gallagher et al., 2003). One reason for those differences can be personal cognitive abilities (Gallagher et al., 2003). There are several studies performed on this topic. A meta analysis of Maan et al., (2012) shows that the effects of cognitive abilities on surgical performance is not clearly investigated until now. This study will concentrate on four cognitive factors which contribute to the performance on the virtual reality simulator showing laparoscopic surgery to a great extent. These are: visuo-spatial ability, spatial memory, reasoning ability and processing speed. Visuo-spatial ability describes the capability to rotate or change mental representations. There is evidence that the visuo-spatial ability of a person affects the performance on the virtual reality simulator (Luursema, Buzink, Verwey & Jakomiwicz, 2010; Ritter, McClusky, Gallagher, Enochsson & Smith, 2006). Luursema et al. (2010) have shown that the visuo-spatial ability can be a predictor for performance on the simulator. It has influence on the duration of the training, the motion efficacy and the damage. Visuo-spatial ability has different aspects (Luursema et al., 2010).

Research has also shown that the spatial relation is a high important factor for laparoscopic surgery (Conrad et al., 2010). Spatial visualization is a factor of visuo-spatial ability (Luursema, 2010). Spatial relation is a predictor for success in laparoscopic surgery. An interesting fact is, that this effect decreases with increased experience of the surgeon, this means that especially the first performances are influenced by spatial relations (Conradet al., 2006). Another cognitive factor influencing the performance of the surgeon seems to be spatial memory. Spatial memory is defined as the ability to record and store information about objects in the environment and where they are. The spatial memory of surgeons is affected through the high load of information they have to remember during a laparoscopic surgery. A higher load of the visual memory affects the capabilities and leads to more errors (Stefanidis
et al., 2007). Spatial memory is closely associated with spatial relations. Conrad et al. (2006) investigated that the abilities for spatial memories are lower when at the same time abilities of spatial relations are affected. During a laparoscopic surgery this can happen when the camera axes are changing (Conrad et al., 2006). The third cognitive factor is perceptual speed. Perceptual speed means the ability to compare things quickly and to identify if they are equal. Perceptual speed seems to influence the learning process of complex tasks which need a high level of speed and precision (Ackerman & Beier, 2007; Luursema, 2010). Furthermore, reasoning ability is a part of the cognitive abilities affecting the performance during laparoscopic surgery. Beginners seem to be affected by this ability in a greater extend because the influence is decreasing with training (Keehner et al., 2006). Therefore it could be expected that beginners with a lower reasoning ability would make more mistakes. We know from investigation that results on this topic are influenced by whether the different cognitive abilities are analyzed on their own, or the effect is measured while some cognitive abilities are working together.

Some of the cognitive abilities are part of the same construct like visuo-spatial ability and spatial memory (Conrad et al., 2006). Therefore it is necessary to measure that. As we have seen from analyzes, the effect of some of those cognitive abilities decreases with more practice (Keehner et al., 2006). Furthermore we know that most of the errors occurring during laparoscopic surgery are happening during the first sessions of a surgeon (Gallagher & Smith, 2003). For this reason the current study is focusing on the first session on the simulator. This is also important for selection and assessment of surgeons. To predict the performance during this first session on the simulator we know from previous studies that two factors seems to have a high influence. Firstly visuo-spatial ability seems to be a crucial factor for beginners. Proven by a lot of studies, the effect reduces with more practice (Luursema, 2010; Keeher, 2006; Luursema, 2012). Secondly spatial memory is an important factor. Spatial memory seems to correlate with the performance of beginners on the simulator (Luursema, 2010). For this reason the aim of this study is to predict the initial performance on a virtual reality simulator with cognitive ability tests measuring the visuo-spatial and spatial ability.

There are already studies that tested the influence of cognitive abilities on surgical performance but the results of those studies are controversially (Maan, Maan, Darzi & Aggarwal, 2012). When testing novice surgeons Wenzel et al. (2003) found a correlation between visuo-spatial ability, surgical performances and the time to complete the tasks. In a different study of Van Herzeele (2010) visuo-spatial ability did not correlate with the initial performance. Groenier, Schraagen, Miedema & Broeders (2013) investigated that visuo-
spatial ability mediates the results in duration and motion efficacy but not in damage. Another study from Luursema et al. (2012) investigated a relation between visuo-spatial ability in damage and motion efficacy. Different studies searching for influence of spatial memory found same controversial results. Hanluck (2002) found a correlation between visual memory and performance during minimally-invasive surgery. Those results are contradictory to the conclusion of a study from Wenzel (2002) who found no correlations. In recent studies Luursema (2010; 2012) showed a relation between spatial memory and the initial performance on a laparoscopic surgery task. Groenier et al. (2013) confirmed those findings. Corrected for the influence of other cognitive variables, spatial memory seems to influence the damage during a simulated laparoscopic surgery. Due to these controversial findings it is even more important to validate the correlation between cognitive abilities and performance.

One reason for the contradictory findings is the use of different methods in those studies (Maan et al., 2012). The researchers used different tests to measure the cognitive abilities and different simulators and tasks to measure the performance during minimally invasive surgery. To replicate the findings of correlations between cognitive abilities and initial performance on a simulator this study will work with methods used in studies from Luursema (2012) and Groenier (2013). These studies are chosen because they are most current on this topic and showed a significant correlation between cognitive abilities and performance on a simulator. Similar to the studies of Luursema (2012) and Groenier (2013) the simulation in this study will be done on a LapSim simulator showing a cholecystectomy procedure. This surgery is chosen for two reasons. The cholecystectomy is one of the most done surgeries and the procedure is good and realistic represented on the simulator (Schijven et al., 2005). To measure the performance on a cholecystectomy procedure two steps of this surgery are chosen: the clip applying and the cutting. Both are available on the LapSim simulator. These two steps are closely related in a realistic surgery and demand different skills and actions during the surgery (Yiasemidou, Glassman, Vasas, Badiani & Patel, 2011). Furthermore, the two steps are suitable as a predictor for the performance on the whole cholecystectomy surgery (Schijven et al., 2003). To measure the cognitive abilities this study will make use of cognitive aptitude tests that were also used in one or both of those studies. Visuo-spatial ability and spatial relations can be tested with the mental rotation test used in both studies (Vandenberg & Kuse, 1978; Luursema, 2012; Gronier 2013). To validate the findings visuo-spatial ability will be also measured with the paper folding test (Ekstrom et al., 1976), used by Groenier (2013). To measure spatial memory we will use the Corsi block tapping test (Corsi, 1972), also used by Groenier (2013). To find out the role of perceptual
speed both studies used the same identical pictures test (Ekstrom et al., 1976; Groenier, 2013, Luursema, 2012), that is why this test is adopted in the current study. The reasoning ability will be measured with the Raven progressives Matrices Advanced (Raven, 1965) used by Groenier (2013).

Knowing the results from former studies, we expect that visuo-spatial ability and spatial memory are the best predictors of initial performance of the first session. Furthermore we expect 1) a correlation between visuo-spatial ability, duration and motion efficacy during the first session and 2) a correlation between spatial memory and the initial performance of damage and motion efficacy.

**Method**

**Participants**

28 students of the University of Twente participated in this experiment. 3 were male, 25 were female. The mean age was 22 (range 19-24). Two of them were left-handed and 9 of the participants reported that they had corrected to normal vision. The participants had no prior experience with laparoscopic surgery. 10 participants reported that they had done a cognitive ability test before. All participants signed an informed consent document (appendix A).

**Materials**

*Cognitive ability tests*

The cognitive abilities tests were adapted computer versions of paper and pen tests. All tests are programed in E-Prime 2.0, except the PicSor test that ran in a separate program.

Reasoning ability was measured with Raven’s Progressive Matrices (Raven, 1965). In this case we made use of the advanced version of the test. In every trail of this test there were 8 symbols which differ from each other by an underlined rule. The participants had to understand this rule and choose one of the 8 symbols which would fit according to this rule.

---

1 Manual

The investigation was done with the "Manual for the Validation of the Twente Endoscopic Skills Test" study. In this handbook all procedural steps are described (See appendix A)
First there were two practice exercises, than the actual test run with 18 exercises with a time limit of 60 seconds per trail. An example is given in Figure 1.

Figure 1: Raven’s Progressive Matrices

Another way to measure spatial relations was the Paper Folding Test. During this test the participants had to fold paper sheets mentally (Ekstrom et al., 1976). A figure presented on the left side of the screen is folded one or more times and punched with several holes. On the right side there were 5 figures of unfolded papers. Participants had to decide which unfolded figure is equal to the folded one on the left side. There were 25 trails with a time limit of 15 seconds per trail. Figure 2 shows the explanation picture of the paper folding test.

Figure 2: Paper folding test
Spatial relations was measured with the Mental Rotation Test (Vandenberg & Kuse, 1978). In this test participants saw two three-dimensional figures consisting of several cubes. The figures are rotated vertically. The participants had to decide whether the figures are identical or whether there exist two different figures. The answer was recorded with a button press on a keyboard, if the figures were different they had to press button v (“verschillend”), if they were equal button z (“zelfde”) had to be pressed. An example is given in Figure 3. The participants had to practice 16 trails with feedback, 96 exercises followed without feedback.

![Figure 3: Mental rotation Test](image)

Spatial memory ability was measured with the Corsi Block Tapping Test (Corsi, 1972). During this test participants had to remember a sequence of 4 up to 9 blocks in different positions lighting up, turning their color from grey to red (Figure 4). After the last square lighted up the participants had to click on the squares in the same order they lighted up in the sequence previously. There were 20 sequences.

![Figure 4: Corsi Block Tapping Test](image)
Perceptual speed was measured with the Identical Pictures tests (Ekstrom et al., 1976). In this test participants had to compare one figure on the left side with 5 figures on the right side and to identify quickly which of those 5 figures is equal to the one on the other side. The figure could be chosen with a click of the mouse cursor on it. The figures were hand drawn and showed for example a face or a house. Participants got 5 practice trails with feedback followed by 96 exercises divided into two blocks. Each block had a total time limit of 90 seconds. An example is given in Figure 5.

![Figure 5: Identical Pictures Test](image1)

Spatial relations was also measured with the Rotating shape test (Cooper, 1975). In this test participants had to rotate figures mentally, but the figures were only two-dimensional and had random outlines. In the same way like in the Mental Rotation Test participants had to press the keyboard buttons v and z after they had decided whether the figures are equal or not. There were six practice trials, followed by 4 blocks of 32 experimental trials with a time limit of 4 seconds per trail. Figure 6 shows two rotating shapes.

![Figure 6: Rotating shapes](image2)

In the PicSOr test which measures the perceptual ability (Gallagher et al., 2003) a rotated cube is presented. A springing arrowhead is touching the surface of the cube. The
participants had to move the arrowhead with the keys “up” and “down” on the keyboard to adjust the position of the arrowhead until the arrow stood perpendicular to the surface of the rotated cube. They had to confirm the position by pressing “Enter” (Figure 7). After the participants could practice 4 trails with feedback they had to do the exercise version consisting of 35 trails.

Figure 7: PicSor Test

Simulator task

The simulator tasks were done in the Experimental Centre for Technical Medicine (ECTM) of the University of Twente. There are three LAPSIM™ simulators running with the software version Surgical Science LAPSIM 2013. This simulator was chosen because research has shown that this surgical simulator has got good construct validity and that it can be useful for the purpose of training and assessment of laparoscopic surgery (Dongen et al., 2006). Visual feedback was provided via a Fujitsu p23-t monitor. The software on the simulator provided information and instructions about every task. The participants could read those instructions or watch videos about the surgery in reality and virtual reality. The experiences on the simulator were divided into two parts: the cutting task and the clip applying task. The participants had to do it on the LAPSIM level “difficult”.
The aim of the cutting task was to grasp a blood vessel, cut different sections of it and release them in a target area. To grasp the vessel the participants had to use a “grasper” with their left hand and to cut different sections of the vessel with “ultrasonic scissors” with the right hand and by pressing a pedal (shown in Figure 8). If this was done successfully the participant was able to move the sections and release them in a target area. The laparoscopic camera was controlled automatically via the computer. When the participant had excised and released 4 sections the task was finished. The participants received feedback of their performance in different categories for example total time, drop failure, stretch damage and whether they had passed the task or not.

![Figure 8: Cutting task](image)

The second task was the LAPSIM Clip applying; objective of this task was to apply two clips at a vessel and to cut the vessel after that. There were different tools as selection in this task. The participants started with two “graspers”. They had to grasp the vessel with one grasper and apply a clip in a highlighted area with a “clip applier” with the other hand. After that they had to change the tools from one hand to the other and apply a second clip. If this was done successfully the participant had to change an instrument into one pair of scissors and divide the vessel into two parts (example given in Figure 9). After the participant had cleaned any blood and removed badly dropped clips the exercise was finished. In this task the camera was also controlled by the computer. After finishing the task the participants got feedback of their performance, for example total time, badly dropped clips, blood loss and stretch damage and whether they had passed the task or not.
Procedure
The whole procedure of this study can be read in the "Manual for the Validation of the Twente Endoscopic Skills Test study" (see Appendix A). The important steps are described in the following. This study was constructed as proficiency based program and consisted of several steps, which can be divided over 2 days. Before starting with the experiment the participants got oral information by the examiner about the procedure of the study (for text see Appendix A). At first the participants had to fill in demographic questionnaire online via surveymonkey.com and needed about 2 minutes. After that the cognitive ability test was administered. The tests run about 45 to 60 minutes. The examiner read a short oral introduction out of the handbook, after that the participants got further instructions about the tests via the program (see appendix A). After having finished the cognitive aptitude tests the participants could have a break of about 10 minutes. Then the surgical simulator task followed. The aim of the simulator task was to pass both surgeries on level “difficult”. After a participant had passed both surgeries he or she could stop immediately. On the first day the participants did 3 sessions on the simulator, each lasting 30 minutes with a 5-minute break between the sessions. Before the first session started they had got a short introduction of the examiner about the program (see appendix A), the surgery and how to handle the simulator. After that they could read further instructions in the program or watch the explanation videos and start with the task. The tasks could be done in a variable order. The participants could decide this. If necessary they got feedback about their performance or ask the examiner.
questions if something was unclear. He could also assist if something was not properly working.

**Data-analyses**
For the analyses of the cognitive abilities tests the proportion scores of the separate tests were used. Those results were transferred to the composite scores of the four variables “visuo-spatial ability”, “spatial memory”, “reasoning ability” and “processing speed”. To measure the performance on the simulator the values of the LapSim were used. The data of the first trail on a virtual reality simulator could represent the influence of the cognitive abilities on the initial performance best (Zhou, Tse, Derevianko & Jones, 2011). That is why they were chosen for the analyses. If other sessions had been used it is possible that effects of learning had changed the results (Zhou et al., 2011). Additionally differencescores between the first and the last trail on the simulator during the first session were used. Three constructs had been measured: time, motion efficacy and damage. The time construct is measured as the total time of the first trail on each task. For motion efficacy two variables out of the LapSim were used. That are the scores of the “angular path” (left and right) and of the “path length” (left and right). To combine both variables they were transferred to z-scores and the mean is used. To test the first hypotheses, visuo-spatial ability and spatial memory are the best predictors for the initial performance on the simulator, a linear regression analysis with the method “enter” was performed. This is to measure how the different tests separately predict the performance. There are different dependent variables to measure the initial performance. That are the duration of the task, the motion efficiency and the total damage. For this analyses data from the simulator were used. There are four independent variables, which can be used to predict the performance on the simulator: visuo-spatial ability, spatial memory, reasoning ability and processing speed. A multiple regression analyses was done additionally, to analyses how all tests together predict the performance. Those analyses were done for the cutting task and also for the clip-applying task.
Results

For the analyses of the cognitive abilities tests the composite score of the four variables “visuo-spatial ability” (M=0.426, SD =0.19), “spatial memory” (M=0.42, SD=0.16), “reasoning ability” (M=0.37, SD=0.17) and “processing speed” (M=0.88, SD=0.08) were used. It seems to be that the distribution of the values in the sample is an approximation of the normal distribution. For an example of the distribution see appendix B. Nevertheless it has to be mentioned, that the sample is not representative for the whole population, because the study is done only among psychology students.

It was checked if there is a difference between the performance of the people who started with the cutting task and those who started with the clipping task. At first it was thought about a t-test, but this was neglected because the majority (24 people) started with the cutting task. For this reason no correction was done. The regression analyses of the tasks were done with all 28 participants, if nothing different is mentioned. At first there were linear regressions done with only one predictor. Secondly there were multiple regressions performed with all predictors together. I decided to report the most relevant results and numbers according to Field (2009).

Linear Regression

Cutting task

Time
The mean time for the cutting task was 432.15 seconds respectively 7.2 minutes (SD= 265 seconds respectively 4.42 minutes). The fastest participant did the task in 140 seconds, the slowest in 1375 seconds (22.92 minutes). The results of the linear regression with dependent variable “Time cutting task” and the independent variables of the cognitive aptitude tests are shown in Table 1. The largest correlation are between the duration of the cutting task and Perceptual speed (r²= 0.061, β=0.247, p=0.205) and reasoning (r²= 0.059, β = 0.242, p=0.216). Visuo-spatial ability correlates rarely with duration (r²= 0.003, β =0.053, p=0.789). The distribution is shown in appendix C and illustrates the relation between visuo-spatial ability and the dependent variable time. This is also the case with a lot of other variables in this study. The results are not significant.

Motion

The regression analyses of motion efficacy during the cutting task are done with z-scores. The range goes from -1.01 up to 3.15. The results can be seen in Table 2. Reasoning ability was the best predictor for the dependent variable motion efficacy in the cutting task ($r^2= 0.092, \beta = 0.303, p=0.15$). There is another correlation between motion efficacy and perceptual speed ($r^2= 0.048, \beta =0.219, P=0.263$). The correlation between memory and motion efficacy is weak ($r^2= 0.00, \beta =0.021, p=0.151$). This is also the case with the independent variable visuo-spatial ability ($r^2= 0.002, \beta =0.046, p=0.814$).

Tissue damage

The mean score of tissue damage during the cutting task is 24.14 (SD=20.86) The minimum and maximum are 3.00 and 79.00. The results of the linear regression indicate a correlation between perceptual speed and the total tissue damage during the cutting task ($r^2=0.156$, $\beta=0.395$, $p=0.038$). This correlation is significant. The distribution can be seen appendix D. The correlation between tissue damage and memory is smaller ($r^2=0.036$, $\beta=0.191$, $p=0.331$). The results are shown in table 3.

Clip applying task

Time

The analyses are done with only 26 participants because the LapSim simulator did not recorded a time for two participants during their first session on the simulator. The fastest person did the clip-applying task in 91 seconds the slowest in 804 seconds (13,4 minutes). The mean is 376 seconds respectively 6,27 minutes (SD=196 seconds). The regression analyses indicate the strongest correlation between visuo-spatial ability and the duration ($r^2=0.018$, $\beta =0.133$, $p=0.517$). The correlation with perceptual speed is similar ($r^2=0.013$, $\beta =0.115$, $p=0.205$). Both correlations are not significant. The correlations are shown in table 4.

Motion

The regression analysis of the motion efficacy during the clip applying task is again done with all 28 participants. The lowest z-score was 0.104 the highest 3.38. The results showing only weak correlations between the dependent variable “Z-score motion efficacy” and the independent variable of the cognitive aptitude tests (table 5). Reasoning ability has the strongest correlation ($r^2=0.077$, $\beta=0.277$ $p=0.153$). Memory has se smallest correlation with motion efficacy ($r^2=0.00$, $\beta=0.080$ $p=0.687$). The correlation with visuo-spatial ability is also weak ($\beta=0.080$ $p=0.678$).

### Damage (badly dropped clips)

The mean of badly dropped clips during the first performance on the clip applying task is 0.65 with a standard deviation of 1.03, a minimum of 0 and a maximum of 4 badly dropped clips during the task. The strongest correlation is between Perceptual speed and badly dropped clips \((r^2 = 0.31, \beta = 0.311, p = 0.188)\). The weakest correlation between visuo-spatial ability and badly dropped clips \((r^2 = 0.00, \beta = 0.088, p = 0.657)\). The correlations are not significant.
During the study an error occurred with the LapSim simulator. For this reason it is possible that the data of the first 11 was influenced by this error. Additionally to the analyses mentioned above, the linear regressions for the clip applying task were performed with the participants, who have done the study after this problem was solved (n=15). The results are not as expected better, but even less significant. Only one relation showed to increase. This was between Perceptual speed and the amount of bad clips (r²= 0,326, β =-0,051, p =0,052).

**Multiple Regression**

To see how predictive all variables together are, there is additionally a multiple regression analysis done. The results are like the results of the simple regression. The best dependent variable was damage. There is only one significant correlation between perceptual speed and damage during the cutting task (β = 0,552, p=0,013). The R = 0,561, gives the value of the corellation coefficent between cognitive predictors together and the outcome damage during the cutting task. The results of the multiple regression of all predicting variables and damage during the cutting task in shown in table 7. Other results were not significant.

Differencecores

To check whether the results are mediated through problems during the first trial on the simulator the analyses are also with difference scores between the first trail on the first session, and the last trail on the first session. There are again simple and multiple regressions done. The results are often like the results of the values from the first trail. There is only one significant correlation between perceptual speed and damage (b=143.381, β= 0.601 , p=0.043). The R = 0.582, gives the value of the corellation coefficient between all cognitive predictors together and the outcome differencesore of damage during the cutting task. The best results gives the multiple regression with all predicting variables and the difference score of damage during the cutting task. There results are given in table 8.

Discussion

The purpose of this study was to find out how cognitive aptitude tests can predict the initial performance on a virtual reality simulator for laparoscopic surgery. One aim was that this information could be used to develop assessment, selection and training for surgeons. The assumption was that the cognitive aptitude variables visuo-spatial ability and spatial memory were the best predictors of the initial performance (Luursema et al., 2010; Ritteret al., 2006). Especially two strong relations have been expected: between visuo-spatial ability and the dependent variables duration and motion efficiency and between spatial memory and the dependent variables damage and motion efficacy. Those expectations were not confirmed with this study. The analyses show that there are few significant correlations between the cognitive aptitude tests and the dependent variables of initial performance. For the cutting task three dependent variables were measured: duration, motion efficacy and tissue damage. The relation between all the dependent variables with visuo-spatial ability is only weak. This means that visuo-spatial ability had no predicting value in the framework of this study. This is a contrast to the findings of Luursema et al. (2010) who found out that visuo-spatial ability can predict the performance on a virtual reality simulator. From further investigation we now that the effect of visuo-spatial memory decreases with more learning (Conrad et al., 2006). For this reason it was expected that visuo-spatial ability would have a strong influence during the first session.

This expectation cannot be confirmed. In the sample of the study the participants were not or rarely influenced by visuo-spatial ability during the cutting and clip applying task. It was a strong correlation predicted between visuo-spatial ability and duration of the task and motion efficacy. This prediction is not in line with our expectation and is contradictory to the findings of Groenier et al. (2013). Similar to the results of the visuo-spatial ability test are the results of the spatial memory test. We know from investigation that a high load of spatial information is leading to more errors (Stefanidis et al, 2007). We expected that spatial memory predicts the performance because during a laparoscopic surgery the surgeons have to remember a high load of spatial information, but spatial memory had no predicting values for performance on the cutting and clip applying task. There is only a weak connection with tissue damage and hardly a relation with motion efficacy, but this influence is not significant. This is in contrast to the findings of Luursema (2010) and Hanluck (2002) who found correlations between spatial memory and performance. Nevertheless the findings are in line with findings from investigation of Wenzel (2012) who found no relation between the
two variables. In the framework of this study other variables had more predicting values than visuo-spatial ability and spatial memory. This was especially perceptual speed.

Both, duration and tissue damage, have the strongest relation with perceptual speed perceptual. The relation between perceptual speed, measured with the identical pictures test, is the only significant relation in the framework of this study. That means to a limited extend, in this study the result of the identical picture test predicted the tissue damage performance during the cutting task. That is interesting in this respect because the investigation showed that perceptual speed is especially an important factor during the learning process and influences the learning curve (Ackerman & Beier, 2007; Luursema, 2010). For this reason we did not expect that perceptual speed would be the best predictor for the initial performance on the cutting task.

The best predictor for motion efficacy was the score of the reasoning ability test, Raven’s Progressive Matrices. This fact underlines the findings of Keehner et al. (2006), who found a effect of reasoning ability among novice which decreases with more learning. The best predictor for damage, measured with badly dropped clips was the score of the PicSor test.

The results of this study stresses the findings of Maan et al. (2012), who investigated that there is a relation between cognitive abilities and surgical performance. This is in line with the theories about the learning of motor activity. Cognitive abilities are often an important factor, also during surgery (O’Neil, Skeel & Ustinova, 2013) The findings are not in line with the expectations and often contradictory to the findings of other studies. This stresses the results of Maan et al., (2012) who investigated that the effect depends on the quality of the study and the chosen tests and tasks. From this results it can be learned, that it is important to distinguish between the initial performance and the learning process. There are variables like reasoning ability, which influence especially the learning process, and other like perceptual speed, which have an effect on both, initial performance and learning process. Whether there is an effect or not seems to be depending on the specific task. The mentioned studies, worked with different tasks on the simulator and it is possible that for this reason they got different results. This could mean that, for example, for the cutting task different abilities are necessary than for the clip applying task. Possibly the measured cognitive aptitudes are not that important for the clip applying task. It would be important to investigate whether there are variables, which have an effect on a lot of tasks. There are several reasons which could cause the controversial findings of this study. One of those reasons could be the sample of the study. The participants of the study were almost only psychology students. Possibly this sample is not representative for persons who are novice on a laparoscopic simulator.
Psychology students have to deal with a lot of cognitive tests, in the framework of their study. 50% percent of the students stated in their questionnaire that they had done a cognitive test before. A study of Ahn & Workman (2012) showed that more experience with spatial relations leads to better results in the Paper Folding Test. Potentially psychology students are as a result of cognitive tests more experienced with factors like visuo-spatial ability and spatial relations. Furthermore the psychology students learn how cognitive tests are constructed and in which way the capabilities are measured. It is possible, that for this reason psychology students get other results in cognitive tests than other people. Additionally it is not sure how valid the computerized versions of the cognitive aptitude tests are. For example, visuo-spatial ability was measured with the help of the Paper Folding test. During this test participants had a lot of questions about it. It seems that the example (see figure 2.) does not properly explain the procedure of the test. Although everybody had got the same explanation, some people asked more questions what they should do. This is quite similar to the PicSor test. A lot of people needed an additional explanation of the examiner. This way the participants received different information, which could have an effect on the cognitive aptitude tests. 

An important factor of this study was the simulator. The study was done on three completely new simulators, which had been installed only a few days before. The program on the simulators was not properly running, which led to different problems. The settings of the clip-applying task were not properly correct, so that it was not possible to pass this task. There was an inexplicable loss of blood, which was could not be stopped by the participant. Through this the data of the clip applying task was influenced in several variables. The participants could have thought that the blood vessel was destroyed and for this reason they used more clips. This fact could have led to a higher score on badly dropped clips. Furthermore it is possible that they searched for the reason of the blood loss which took a longer time for this task. To find the reason of the blood loss and to stop it, they could have moved the instruments more often which could have led to a higher score on motion efficacy. The fault of the system was only discovered after the first 13 participants had done the study. It is not certain if this error concertinaed all participants. Additionally the simulator different graphic errors occurred. Maybe that those errors caused confusion, and so wrong scores on the dependent variables of the simulator. An additional factor is that the participants did the study under different circumstances. The first students who did the study were in the room alone with the examiner and sometimes with another participant. Later during this study the room and other simulators were needed for lessons. So it was very busy and noisy in the room. Possibly this influenced the concentration and accuracy of the
participants and influenced the results.

The aim of this study was to predict the performance on a laparoscopic simulator with the help of cognitive tests. The findings made are not in line with the expectations. Not visuo-spatial ability and spatial memory were crucial factors, but perceptual speed seems to be a predictor for laparoscopic surgery. For this reason it is important to continue the investigation, in order to understand the relation between this cognitive factor and dependent variables. It would be useful to choose an other than the clip applying task, because it seems to difficult to measure the dependent variables with this task. Although the findings cannot be used for the selection of surgeons or to develop training programs for them, they showed that there exist connections between cognitive abilities and performance. The relation seems to be very complex. The studies that exist at present on this topic are done with a lot of different methods. This leads to different results between the studies. To get more and really certain information about this it is important to work with exact the same method, valid cognitive tests and on a valid, properly working simulator. It is possible that the results of these studies would have been others if the sample had been more random and the virtual reality simulators had worked better. For this reason it would be necessary to repeat these studies with both variables.

Department of Technical Medicine
² University College of Cork
Department of Medical Education
Requirements

Prior to testing make sure that the conditions listed below are satisfied. Make sure that you have reserved the pc room and the lapsim room.

For the demographics questionnaire:
1. Check the internet connection and a web browser (e.g. Internet Explorer).

For the cognitive aptitude test battery:
1. Check that the runtime version of E-prime (called E-Run) installed on the desktop:

   ![E-Run](image)

   a. If E-run is not installed:
   b. Click on the Windows logo on the bottom left in the taskbar.
   c. Select E-prime from the list of programs and click once.
   d. Select E-run and right click.
   e. Select ‘Send to’.
   f. Select ‘Desktop (create shortcut)’.

2. Check that the PiCSor test program is installed on the desktop:

   ![PiCSor](image)

   a. If the program is not installed or not working properly:
   b. Go to the D-drive (via Windows logo -> Computer).
   c. Open the folder ‘Validatie TEST’.
   d. Open the folder ‘Win9x’.
   e. Open the folder ‘Dist’.
   f. Double click on the ‘setup’ file with the extension ‘Application’.
   g. The installation program for PicSOR starts:
      i. Click on ‘OK’
      ii. Click on the setup icon (top left of the setup screen)
      iii. Click on ‘Yes’
      iv. Click on ‘Yes’
      v. Click on ‘Ignore’
      vi. Click on ‘OK’
   h. Go back to the ‘Validatie TEST’ folder.
   i. Open the ‘WinNT Distribute’ folder.
   j. Right click on the file ‘picsor32’ with the file extension ‘Application’.
   k. Select ‘Send to’ from the drop-down menu.
   l. Click on ‘Desktop (create shortcut)’.
   m. Go back to ‘Desktop’ and check that a shortcut is made (see figure above).
For the laparoscopic simulator tasks:
1. Pick up the key to the simulator room from the ECTM desk or ask the assistant to let you in the room. If you get the key, make sure to activate it (ask desk assistant for instructions).
2. Check that the power to the simulator computer is on (socket on the left of the computers).
3. Log in with the lapsim account (login and password are printed on the keyboards).
Study Purpose and Design

The purpose of the current study is to examine the relationship between cognitive attributes and performance of basic laparoscopic tasks on a simulator. Participants are: 1) technical-medical students, biomedical students or psychology students 2) who have no prior experience in performing laparoscopy or with performing laparoscopic tasks on a simulator. The study consists of two parts across two consecutive days:

1. A cognitive attributes test battery of approximately 45 minutes;
2. Practice of basic laparoscopic tasks on a virtual reality (VR) simulator for a maximum of six sessions lasting 30 minutes each and 5 minute breaks in between.

Timeline of the study

On the first day, the cognitive attributes test battery is administered and there are three practice sessions on the VR simulator. Together, the cognitive attributes tests and the practice sessions last about 2.5 hours. On the second day, there are the remaining three sessions on the simulator, lasting about 2.5 hours as well. However, if a participant reaches a certain predefined level on the laparoscopic tasks before the last session, practice is terminated. See the figure below for a schematic representation of the study’s procedure. This means that the exact duration of the study depends on how quickly a participant reaches a certain level on the laparoscopic tasks.

Figure 1. Schematic representation of the study timeline.

Below, you will find more information on the cognitive aptitude test battery and the laparoscopic tasks on the simulator.

Cognitive aptitude test battery

The cognitive attributes test consists of several validated psychological tests measuring visuo-spatial ability, reasoning, short term memory, speed of information processing and perceptual ability. Previous research suggests that these abilities are related to performing and learning
laparoscopic tasks. Some of these tests require a high level of accuracy, others require a speeded response. Each test has a certain time limit.

**Virtual Reality laparoscopic tasks**

Two basic laparoscopic tasks are practiced on a virtual reality simulator (the LapSim Surgical Science simulator). The tasks are part of the laparoscopic cholecystectomy procedure, however, participants do not practice the entire procedure. Participants practice two tasks (Cutting and Clip Applying) and practice each task several times during a session. After half an hour there is a 5 minute break before the next session. All tasks are practiced at the same difficulty level during each session.
Running the experiment

Prior to the experiment
Make sure you bring an information leaflet so you are able to answer questions that the participant might have.
Make sure you have enough copies of the informed consent form (see Appendix A) and some extra ones in case someone makes a mistakes and needs to fill out a new form.
Make sure you know which participant number to assign to the current participant(s).
Make sure you are present at least half an hour before the participant starts the experiment to check whether the equipment is working.

Participant anonymity
As soon as a participant agrees to take part in the study, he or she is assigned a participant number. This number will be the linking code between the personal information of each participant and the actual data, such as the scores on the cognitive aptitude tests and performance measures on the simulator. This code will be used instead of, say, a participant’s name to guarantee participant anonymity. In data analysis the test scores are combined with the performance scores of each participant through this code.
Make sure that each participant receives a unique number. Keep track which numbers have already been used! This number needs to be filled out by the participant on several occasions:

- The informed consent form
- The demographics questionnaire
- The cognitive aptitude test battery. Note: for the PiCSor test participants cannot fill out the participant number themselves, this has to be saved in the filename of the PiCSor file by the experiment leader (i.e. you).
- The LapSim simulator

Informed consent
First, participants sign an informed consent form. THIS IS VERY IMPORTANT! Every participant needs to sign an informed consent form prior to starting the study. If a student does not want to sign the informed consent form, he or she cannot participate in the study! An example of the informed consent form can be found in Appendix A.
Make sure you have enough copies of the informed consent form available. Also, make sure that you fill out the participant number on each informed consent form.

Demographics questionnaire
Second, participants fill in an online demographics questionnaire. This questionnaire contains questions about:

- Participant number
- Gender
- Date of birth
- Nationality
- Handedness
- Impaired sight (e.g. glasses)
- Colour-blindness
- Dyslexia
• Video gaming experience
• Prior experience with cognitive aptitude testing

The questionnaire is supported by Survey Monkey. You can access the questionnaire as follows:
1. Open a web browser, e.g. Internet Explorer
2. Type in the address: http://www.surveymonkey.com/s/validatieTEST
3. Press Enter
4. The questionnaire starts (check whether it opens in a new window). You should see the screen displayed in figure 2.

Figure 2. Screenshot demographics questionnaire in SurveyMonkey.

After the participant finished the demographics questionnaire, proceed with the cognitive aptitude test battery, see next chapter.

Instructions for the participant
Make sure that the participant is sitting comfortably behind the computer. Adjust chair height or screen position if necessary. Give the following instructions to the participant:

This study consists of several parts, as explained in the information leaflet. First, I need you to sign an informed consent form. [Give informed consent form and make sure that participant signs it. Write down participant number on form.] Next is a demographics questionnaire asking about personal information, such as your age and handedness. This is an online questionnaire and only takes about two minutes to fill in. After that, the TEST battery will start. The TEST battery consists of two parts. The first part will last about 45 minutes, the second part lasts about 5 minutes. You will receive additional instructions as soon as you start the first and second part, either on the screen or from me. Do you have any questions thus far? [Participant starts with the demographics questionnaire.]
The Twente Endoscopic Skills Test (TEST)

The TEST battery consists of two parts and each part runs in a separate program. The first part of the TEST battery runs in a program called E-prime. E-prime is a licensed program (see [http://www.pstnet.com/eprime.cfm](http://www.pstnet.com/eprime.cfm)) and specifically developed to design psychological experiments. Once you’ve confirmed that the correct runtime version of E-prime is installed on the pc (see chapter Requirements), you are ready to start the first part of the TEST battery. The first part of the TEST battery lasts about 45 minutes.

1. Start up computer(s).
2. Log in with your own account.
3. Click on the Windows logo in the menu on the left bottom part of the screen.
4. Fill in at Search programs and files: Truecrypt.
5. Open the Truecrypt program
6. Select the drive letter “T:”
7. Click on ’select file’.
8. Click on the C-drive.
9. Open the “TGfiles” folder.
10. Open the “TG-CVT 2013” folder.
11. Select the file ‘TG-CVT 2013.dmp’.
12. Click on ‘mount’.
13. Select ‘display password’.
14. Fill in the password: =4TG-C0gn1t13v3-V-T3st!
15. Minimalise the TrueCrypt window and close all other windows.
17. If you get an error message (cannot find file or something like it), just ignore and click it away.
18. Click on ‘browse folder’ (see red square below):
19. Open the T-drive (via Computer).
20. Open the “preTEST - 2013” folder.
21. Select the file: “pre_TEST V2 UT – NL”. This file has a Script extension. Click on ‘open’.

22. Now give the participant the following instructions:

This TEST battery consists of two parts: the first part lasts about 45 minutes and the second part about 5 minutes. The TEST battery measures several cognitive abilities that are related to learning basic laparoscopic tasks. The abilities measured are: visuo-spatial ability, working memory, reasoning, speed of information processing and perceptual ability. The goal of this research is to find out which of these abilities best predicts performance on a laparoscopic simulator. This will help to assess and select surgeons in the future.

The first part of the TEST battery consists of several subtests. Each test starts with instructions on the screen and one or more practice or sample exercises. Each of the tests in the first part of the TEST battery have a certain time limit which will announced in the instruction on the screen. Please read these instructions carefully and if anything is unclear just ask me.

It is important to work as fast and as accurate as possible. Some tests or exercises might be more difficult than others, please try to complete as many exercises as possible. This will increase the reliability of your results and the assessment of your actual ability.

I will be around to assist you if needed.

23. Click on ‘Run’.
24. The start-up screen of the cognitive aptitude test battery in E-prime should now open asking for the participant number.
25. Make sure the participant fills in the correct participant number (see the informed consent form that was filled in) and continues with the first part of the cognitive aptitude test battery.

You can give technical assistance during the test, however, feedback on a participants performance is not allowed. For example, if a participant asks ‘Is this the correct way to solve the exercise?’ you can reply ‘Try to perform at the best of your abilities.’

After the last exercise of the first part of the TEST battery a ‘thank you’ screen will appear. The participant is asked to call for the assistant and when the spacebar is pressed, the participant leaves the program and the test results are automatically saved.

You can now start part two of the TEST battery, which is described in the next chapter.
The PiCSor test

The second part of the TEST battery is the PiCSor test which runs in a programming environment specifically designed for this test.

1. Go to the ‘Desktop’.
2. Double click on the PicSoR icon:
3. Select ‘Practice’ at Run type.
4. Select ‘Cube and arrow’ at Experiment.
5. Now give the following instructions to the participant (see also Appendix C):

   This is the second part of the TEST battery. The PicSoR test measures perceptual ability. This test measures your ability to assess depth in a 3-dimensional picture. On each exercise, you will see a cube tilted at a certain angle. The point of a spinning arrowhead is touching the surface of the cube. You adjust the arrow until its shaft is perpendicular to the cube’s surface at the point where they touch. The actual angle of the tilted cube is compared to your estimated angle as indicated by the positioning of the arrowhead’s shaft.
You can use the ‘up’ and ‘down’ arrow keys on your keyboard to adjust the shaft of the spinning arrow. You can press ‘Enter’ as soon as you have positioned the arrowhead. You can click on ‘Next’ to continue to the next exercise. It is important that you work as fast and accurate as possible.

   First, there are four practice exercises with feedback.

6. Click on ‘Run’.
7. Click on ‘Next’ to continue with the next (practice) exercise.
8. After the participant has completed the fourth practice exercises, you need to click ‘Quit’, otherwise the practice session never ends. You should now automatically return to the main screen of the PicSoR program.
9. Select ‘Experiment’ at ‘Run type’.
10. Now give the following instructions to the participant (see also Appendix C):

    The actual test consists of 35 exercises. Work as fast and as accurate as possible! There is no time limit for this test, but speed is important.

11. Click on ‘Run’.
12. A new window opens to indicate where you can save the file with the results from the experiment.
    a. Go to D-drive.
b. Open the folder ‘Validatie TEST’.

c. Open the folder ‘TEST UT’.

d. Open the folder ‘Participants’.

e. Type in the window at ‘File name’ the date followed by the participant number, as follows: date_participant number. For example, if the date is 7 June 2012 and the participant number is 12100 the file name should look like this: 20120607_12100. The date always starts with the year (in this case 2012), then the number of the month (06 for June) and finally the day (07). Make sure you always use 4 digits to indicate the year and always 2 digits for the month and day (so include a 0 for the months January through September and for the first 9 days of the month).

**Note:** THIS IS VERY IMPORTANT! This filename is the only way to link a participant to the other test scores, such as the other aptitude tests, the performance on the simulator and the demographics questionnaire!

f. Click on ‘Save’.

g. The participant can start with the first exercise of the test.

h. After the last exercise (see the number at the top left of the screen) the program stops and returns to the start-up screen.

i. Click on ‘Quit’ to close the program.

This was the last exercise of the cognitive aptitude tests. In the next chapter the procedure for the simulator sessions is described.
Practice sessions on the simulator: participant’s first session

When you have a new participant that will practice on the lapsim simulator for the first time, follow the steps below. If you have a participant that has already done one or more sessions on the lapsim simulator (and now returns for part two), continue with the next chapter “Practice sessions on the simulator”

Make sure that you prepare a first session with a new participant beforehand:

1. Make sure you have fulfilled the requirements described in the chapter “Requirements”.
2. After starting up the computer, double click on the lapsim 2013 icon on the desktop.
3. Log in the lapsim environment as a teacher: User Name = teacher, Password = teacher.
4. Only for the computer on the left: make sure that 3D vision is disabled:
   a. After login: go to Settings.
   b. Click on the tab ‘Graphics’.
   c. Select ‘No stereo’ from the drop down menu under the heading ‘Stereoscopic 3D’.
   d. Click on ‘OK’.
5. Click on the “Student” button at the left bottom part of the screen.
6. Select “Create new student”.
7. Fill in the Login Name (preferable the same participant number used for the cognitive ability tests) and Password (preferably something that is the same for all participants and easy to remember).
8. Select the new participant from the list of participants (blue emphasis).
9. Click on the “Assign courses” button (bottom right of the screen).
10. Select the course “TG difficult” from the list on the left side of the screen.
11. Click on ‘Add’.
12. The course “TG difficult” should now appear on the list on the right side of the screen.
13. Click on “Finish”.
14. Log out using the Logout button at the top of the screen.
15. Log in using the user name and password just assigned for the new participant (see step 6 previously).
16. You should now see an overview of the LapSim system.
17. Place the two instruments into the tracking balls of the simulator (the middle ball, for the camera, is not used).
18. Make sure that the participant is standing in front of the simulator correctly: arms at approximately a 90 degree angle, loose wrists and loose shoulders. The participant will be in this posture for quite some time, so make sure he or she is comfortable. Adjust table height if necessary. This can be adjusted during practice as well, if necessary.
19. Now give the following instructions:

You are about to start practicing two basic laparoscopic tasks which are part of a procedure called cholecystectomy, cutting and clip applying. You can read the instructions for each exercise and view videos of performance of these tasks during an actual procedure as well as in the virtual environment. You can alternate between the two exercises of cutting and clip applying.
Sometimes it helps to practice a different exercise for a while. I advise you to practice both exercises at least once during each session. Please try to complete each exercise each time you try it, even if you feel that it is pointless to continue. If you feel that you cannot continue with an exercise no matter how hard you try, you can click on the ‘Exit’ button on the bottom right of your screen. During the exercises you will get instructions from a virtual tutor at the bottom left of the screen. If you don’t remember what to do next, you can always look at the hint currently provided by your virtual tutor. Do you have any questions at this time?

20. The participant can now click on one of the two exercises in the menu on the left.
21. The participant can read the instructions on the screen. N.B. There is more than one screen with instructions. Participants can click on the buttons on the bottom left of the screen to read further instructions.
22. Start practice by clicking on the ‘Start’ button at the bottom of the exercise menu.
Practice sessions on the simulator

These instructions are for participants who have already practiced one or more sessions on the simulator. If you have a new participant, please read the previous chapter “Practice sessions on the simulator: participant’s first session”.

1. Make sure you have fulfilled the requirements described in the chapter “Requirements”.
2. After starting up the computer, double click on the lapsim 2013 icon on the desktop.
3. Login with the account you have created previously for this participant (User Name = participant number).
4. Explain the participant that he or she practices the same two tasks (cutting and clip applying) until proficiency is reached (i.e. ‘passed’ the exercises). A session lasts half an hour and each session is followed by a 5 minute break. The experiment will automatically end after 5 sessions (including the sessions performed the first time).
5. The participant can now double click on either one of the exercises (cutting and clip applying) on the left side of the screen and start practice.
Data processing

Demographic questionnaire
The data from the demographic questionnaire can be accessed through SurveyMonkey (www.surveymonkey.nl). Login = ECTM; password = ECTMTG. The study is called Demografie Validatie TEST. You can export data through ‘Resultaten analyseren’ and ‘Reacties downloaden’.

TEST battery E-prime
1. Save the txt and edat files that were created on the T-drive to another location (e.g. a usb-stick or drive D).
2. Go to the folder that contains the txt and edat files of the current participant.
3. Double click on the edat file and the E-DataAid program should start up.
4. Click on “File”.
5. Click on “Export”. Select: Export to Excel.
6. Click on “OK”.
7. Save the file in the same folder as: Score_[participant number]. For example: Score_12345.
8. A csv or txt file should now be made in this folder.
9. Open the csv or txt file in Excel.
10. Remove the top row.
11. Save file: File -> Save as -> Save as type: CSV (Comma delimited).
12. Copy all the csv files to a separate folder, preferably on drive C.
13. Open a cmd window: select the folder with all the csv files -> click the right mouse button -> open command window. Or: click on Windows logo in taskbar -> type in Search programs and files cmd -> enter -> go to the correct folder with the csv using the ‘cd [subdirectory]’ command.
14. Type in: gawk –F; -f extract_boxplot_data.awk Score_(file name).csv > XScore_(file name).csv (XScore_(file name).csv = extractfile, file name should be participant number).
15. Repeat step 14 for every csv file (tip: use tab and arrow up/down to select command lines).
16. Check if there is the right number of XScore files in the folder.
17. Type in the command window: gawk –F; -f CVTqqT_out.awk Xscore_(file name).csv.
18. Check that new datafiles were created with the names: all_data.csv en some_data.csv or that new lines were added to these files.
19. Repeat step 18 for each participant.

PicSOr
The data from the PicSOr test are stored as .cae files. These can be read in Excel.
1. Start up Excel.
2. Click on File.
3. Click on Open.
4. Select the PicSOr file you need.
5. Select ‘Fixed width’.
6. Click on ‘Next’.
7. Click on ‘Next’.
8. Click on 'Finish'.
9. You should now have a file with 5 columns and 36 rows.

The score on the PicSOrr test is the correlation between variables RSSLA and OSSLRA. You can calculate this correlation (and transfer it to your own data file) by:
1. Select an empty cell in the Excel worksheet with the PicSOrr data.
2. Click on the formula-symbol in the formula bar.
3. Type in the search bar: pearson.
4. Select the PEARSON function by clicking on OK.
5. Select the 35 values of RSSLA for array 1.
6. Select the 35 values of OSSLRA for array 2.
7. Click on OK.
8.
Troubleshooting

E-prime
E-prime crashes sometimes (for no reason). If E-prime crashes:
2. Explain to the participant he or she can continue with the experiment. If the participant states that he or she would not like to continue the experiment, explain the options stated at item 8.
3. Write down on a paper with the participant number at which test E-prime crashed.
4. Start the E-prime program again (through E-run).
5. Give the participant a different participant number. Write this number down also, so the two datafiles can be combined afterwards.
6. Click through the cognitive aptitude test battery quickly (!) until you reach the test where E-prime crashed.
7. Ask the participant to continue with the test.
8. If E-prime crashes a second time with the same participant, suggest the following options: 1) the participant can continue the test again (following the same procedure above), 2) the participant returns on a different time and/or date to redo the whole test, 3) the participant withdraws from the experiment (participant does not receive credits). Options 1 and 2 are preferred of course.
SAMPLE INFORMED CONSENT FORM

CONSENT BY SUBJECT FOR PARTICIPATION IN RESEARCH PROTOCOL

Section A

Protocol Number: ________________  Participant Name: ________________

Participant Number: ____________

Title of Protocol: Validation of the Twente Endoscopic Skills Test

Doctor(s) Directing Research: dr. Marleen Groenier, dr. Patrick Henn, prof. dr. Anthony G. Gallagher
Phone: +353-21-490-3000 (dr. Henn)

You are being asked to participate in a research study. The researchers at University College Cork study the design and effects of medical education programs. In order to decide whether or not you want to be a part of this research study, you should understand enough about its risks and benefits to make an informed judgment. This process is known as informed consent. This consent form gives detailed information about the research study, which will be discussed with you. Once you understand the study, you will be asked to sign this form if you wish to participate.

Section B
I. NATURE AND DURATION OF PROCEDURE(S):

The purpose of the current study is to examine the relationship between cognitive attributes and performance of basic laparoscopic tasks on a simulator. You can participate if you are: 1) a medical student and 2) have no prior experience in performing laparoscopy or with performing laparoscopic tasks on a simulator.

The study consists of two parts across two consecutive days:
1. A cognitive attributes test of approximately 45 minutes;
2. Practice of basic laparoscopic tasks on a simulator for a maximum of six sessions lasting 30 minutes each.

Timeline of the study

On the first day, the cognitive attributes test is administered and you have three practice sessions on the laparoscopic simulator. Together, the cognitive attributes tests and the practice sessions last about 2.5 hours. On the second day, you have the remaining three sessions on the laparoscopic simulator, lasting about 2.5 hours as well. However, if you reach a certain level on the laparoscopic tasks before the last session, practice is terminated. See the figure below for a schematic representation of the study’s procedure. This means that the exact duration of the study depends on how quickly you reach a certain level on the laparoscopic tasks.

Timeline of the study:
**Day 1**

Inform consent form

Cognitive aptitude test

Practice session 1 on simulator

5 min. break

Practice session 2 on simulator

5 min. break

Practice session 3 on simulator

Level achieved? Exit study.

**Day 2**

Practice session 4 on simulator

5 min. break

Practice session 5 on simulator

5 min. break

Practice session 6 on simulator

Level achieved? Exit study.

Level achieved? Exit study.

Level achieved? Exit study.

End of study.

Cognitive attributes test

The cognitive attributes test consists of several validated, psychological tests measuring visuo-spatial ability, reasoning, short term memory and speed of information processing. Previous research suggests that these abilities are related to performing and learning laparoscopic tasks. Some of these tests require a high level of accuracy, others require a speeded response. Each test has a certain time limit. A researcher of the project is present during test taking, gives you further instructions and answers any questions you have about the tests.

Laparoscopic tasks

Two basic laparoscopic tasks are practiced on a virtual reality simulator. The tasks are part of the laparoscopic cholecystectomy procedure, however, you do not practice the entire procedure. You can practice each task several times during a session. After half an hour there is a 5 minute break before the next session. All tasks are practiced at the same difficulty level during each session. A researcher of the project is present during the sessions, gives you further instructions and answers any questions you have about the tasks.

II. POTENTIAL RISKS AND BENEFITS:

The results from this study will help us to better design our training programs for surgical education on laparoscopy. Furthermore, in the future, a cognitive attributes test could be used to select surgeons for minimally invasive training programs, alongside interviews, assessments and grades. A possible risk is fatigue during the study. We have planned many breaks between sessions to avoid fatigue. Also, you may quit the study at any moment without providing any reasons for your withdrawal from the study.

III. POSSIBLE ALTERNATIVES:

Your participation is voluntary. You may choose not to participate.

**Section C**

**AGREEMENT TO CONSENT**

The research project and procedures associated with it have been fully explained to me. All experimental procedures have been identified and no guarantee has been given about the possible results. I have had the opportunity to ask questions concerning any and all aspects of the project and any procedures involved. I am aware that participation is voluntary and that I may withdraw my consent at any time. I am aware that my decision not to participate or to withdraw will not restrict my access to health care services normally available to me. Confidentiality of records concerning my involvement in this project will be maintained in an appropriate
manner. When required by law, the records of this research may be reviewed by government agencies and sponsors of the research.

I understand that the sponsors and investigators have such insurance as is required by law in the event of injury resulting from this research.

I, the undersigned, hereby consent to participate as a subject in the above described project conducted at the Cork Teaching Hospitals. I have received a copy of this consent form for my records. I understand that if I have any questions concerning this research, I can contact the doctor(s) listed above. If I have further queries concerning my rights in connection with the research, I can contact the Clinical Research Ethics Committee of the Cork Teaching Hospitals, Lancaster Hall, 6 Little Hanover Street, Cork.

After reading the entire consent form, if you have no further questions about giving consent, please sign where indicated.

APPENDIX B: INSTRUCTIONS IN E-PRIME FOR 'TEST V1 UCC'

Introduction

Welcome!
This is the Twente Endoscopic Skills Test (TEST). This test consists of several subtests measuring visuospatial ability, memory, reasoning and perceptual speed. These abilities are related to the performance of minimally invasive surgical procedures.
Each subtest starts with a short instruction and one or several practice exercises (with feedback). It is important that you work as fast and accurate as possible. Each subtest has a time limit which will be announced in the instruction. Some exercises will be more difficult than others. Please try to complete as many exercises as possible.
Press the SPACEBAR to continue.

Raven’s Progressive Matrices Advanced

The first test is an adapted version of the Raven's Advanced Progressive Matrices test. This test measures observation skills and thinking clearly. Each exercise shows a pattern with three rows of three figures. On the third row, the last figure is missing. Below the pattern, 8 figures are shown that might fit the pattern. Examine the pattern and decide which of the 8 figures is needed to complete the pattern, both horizontally as well as vertically.
Press the corresponding number (1 - 8) belonging to the figure you think completes the pattern best. There is only one correct alternative for each exercise.
Next, there are two practice exercises. After each practice exercise you will receive feedback on your answer.
<practice trials>
Press SPACEBAR to continue with the two practice exercises.
Next, there are 18 exercises of the actual test. You will no longer receive feedback on your answers.
The time limit is 60 seconds per exercise.
Work as accurate and fast as possible.
Press the SPACEBAR to continue with the actual exercises.

Paper Folding

This was the last exercise of the first subtest.
The second subtest is an adapted version of the Paper Folding test. This test measures the ability to mentally represent spatial relations of objects.
In each exercise of the test there are some figures drawn at the left and 5 others at the right of the screen. The figures at the left represent a square piece of paper being folded and the last of these figures has one or two small circles drawn on it to show where the paper has been punched. Each hole is punched through all the thickness of the paper at that point.
One of the 5 figures at the right shows where the holes will be when the paper is completely unfolded.
Press the SPACEBAR to continue with the instruction.
<practice slides>
In these exercises all of the folds made are shown in the figures at the left, and the paper is not turned or moved in any way except to make the folds shown in the figures. Remember, the answer is the figure that shows the position of the holes when the paper is completely unfolded.
There are 20 exercises divided across 2 blocks of 10 exercises. There are no other practice exercises with this test and no feedback on your answers.
The time limit for each exercise is 25 seconds.
Press the SPACEBAR to continue with the actual test.

<first block>
Press the SPACEBAR to continue with the next block.

**Mental Rotation Test**

This was the last exercise of the Paper Folding test. The next subtest is an adapted version of the Mental Rotation Test and measures the ability to mentally rotate objects.

In each exercise you see 2 three-dimensional figures made of several connected cubes. You have to decide whether the figures are identical, but one of them is rotated around the vertical axis, or that they are two different figures.

If the figures are identical, press the button 'i' on the keyboard. If they are different, press the button 'd' on the keyboard.

There are 16 practice exercises. After each exercise you will receive feedback on your answer. Place your index fingers on the corresponding buttons.

Press the SPACEBAR to continue with the practice exercises.

<practice trials>
This was the last practice exercise.
There are 96 exercises in the actual test divided across 4 blocks of 24 exercises. You will no longer receive feedback on your answers.

The time limit is 6 seconds for each exercise. Work as fast and accurate as possible.

Place your index fingers on the corresponding buttons 'i' and 'd'.

Press the SPACEBAR to continue with the actual test.

<block 1>
Press the SPACEBAR to continue with the next block.

<block 2>
Press the SPACEBAR to continue with the next block.

<block 3>
Press the SPACEBAR to continue with the next block.

<block 4>

**Corsi Block Tapping Test**

This was the last exercise of the Mental Rotation Test. The third subtest is an adapted version of the Corsi Block Tapping Test. This tests measures spatial short term memory. Each exercise consists of a pattern of nine grey squares. One by one these squares change colour, from grey to dark red back to grey. They change at a rate of one square per second. After the last square has changed colour the nine squares turn into the colour black.

Now you can click on the squares with your mouse cursor in the same order that they turned red previously. The sequences of squares turning red can be 4 to 9 squares long.

Please note: when you click on the squares, they will NOT change colour, make sure you click each square only ONCE and do NOT press any keys on the keyboard! If you have finished your sequence, but the next trial does not start you have not yet clicked on the right number of squares and need to click additional squares.

Next, there is 1 practice exercise WITHOUT feedback on your answer.

Press the SPACEBAR to continue with the practice exercise.

<practice trial>
This was the practice exercise.

The actual test consists of 18 exercises. The sequences of squares turning red can be 4 to 9 squares long.

Please note:
1. Make sure that you position the mouse cursor clearly WHITHIN the squares.
2. When you click on the squares, they will NOT change colour.
3. Make sure you click each square only ONCE.
4. Do NOT press any keys on the keyboard!
5. If you have finished your sequence, but the next trial does not start you have yet not clicked the right number of squares and need to click additional squares.
Press the SPACEBAR to continue with the actual test.

**Identical Pictures**

This was the last exercise of the Corsi Block Tapping Test. The last subtest is an adapted version of the Identical Pictures test. This test measures your ability to pick the correct object quickly. On each trial, you will see six objects on one row in the middle of the screen. One object is on the left side of the row and five objects on the right side.

Determine which of the five objects on the right side is the same as the object shown on the left. Click on the object that you think is the same with your mouse cursor. It is important to work as quickly and accurately as possible!

There are five practice exercises with feedback on your performance.
Press the SPACEBAR to continue with the practice exercises.

<practice trials>

This was the last practice exercise.
There are 96 exercises in the actual test divided across 2 blocks of 48 exercises. You will no longer receive feedback on your answers.
The time limit for each block is 90 seconds. Work as fast and accurate as possible.
Press the SPACEBAR to continue with the actual test.

<block 1>

Press the SPACEBAR to continue with the next block.

<block 2>

**Thank you**

This was the last exercise of the Identical Pictures test.
Thank you for your participation!
Press the SPACEBAR to exit the program.
Please ask the assistant for further instructions.
